1 Introduction

Every social issue surrounding us today stems from complex factors. Now we need to establish a trans-disciplinary approach so that we can examine the flow of interconnected phenomena. The solution lies with new methodology called agent-based modeling. This concept makes it possible to model our society as a system formed by an interaction between numbers of autonomous agents.

In the current state in the study of simulating agent-based economic models, however, there is a problem that needs to be resolved. That is the absence of integrated environment to support a whole research process from conceptual modeling to simulation analysis. The problem did not become serious too much up to now, because the models were small-scale and for experimental use. It becomes, however, indispensable to resolve the existing problem, as the simulations come to be used practically in social science, policy analysis, and business field.

In this paper, we propose a new development process, which we call “Model Driven Development”. To realize the process, we also propose tools that help us build the conceptual models and simulation models. Then, the simple trade model is introduced as the example in the last part of the paper.

2 Background

2.1 Supporting Systems for Simulation Development

In the last some years, several languages, frameworks and tools for agent-based simulations have been proposed. For example, “Swarm Simulation System”, which seems to be the most famous and to be used, provides the class library for the simulation of complex adaptive systems [Minar et al., 1996]. As well as Swarm, “RePast” provides the class library to make the agent-based model [Collier, 2003]. “Ascape” also provides the framework, and it is said that the amount of the code description can be less than that of Swarm and RePast [Parker, 2001].

These support systems try to solve the problem with a necessary support to the modeler who has a little (or, no) experience of the computer programming. As the solution, those systems assist the modelers to write programs by providing a general library and framework. In fact, these systems are useful for the reduction of programming. They, however, would not support for the modelers to do conceptual modeling. We would like to emphasize that it is important to support modeling as well as to support programming. Thus, we need a new system that helps us build the conceptual models and simulation models.
2.2 Model Driven Development: A New Paradigm of Software Development

In the field of software engineering, there is a trend toward considering the design models as the development artifacts that contribute directly to software development. “MDA” (Model Driven Architecture) and “Executable UML” (Unified Modeling Language) are proposed for the Model Driven Development [Frankel, 2003, Mellor and Balcer, 2002, Kleppe et al., 2003]. The point is “using modeling languages as programming languages rather than merely as design languages.” [Frankel, 2003]. As a result, “It makes it possible to raise the level of abstraction for software development” [Frankel, 2003] (Figure 1). History tells that the productivity and quality are improved in consequence of raising the level of abstraction.

The traditional development process of software models is driven by implementation, it means program coding (Figure 2). In the traditional development process, the transformation from design models to program codes is done by hand. According to the process, the modeler should write a lot of program codes. In this sense, design model is said to be “just paper” [Kleppe et al., 2003] and “blueprint” [Mellor and Balcer, 2002].

On the contrary, the emerging concept of software development process is driven by modeling (Figure 3). We can use more high-level language for development, instead of writing in the lower-level language. It means that a modeler describe the models rather than program codes. Therefore, the modeler can concentrate on modeling without considering the software implementation, because the program code will be an exact translation of the design model. In this sense, the design model is no longer “just paper” and “blueprint”.

In this paper, we propose process and tools for Model Driven Development of agent-based social simulations.

3 Proposed Process based on Model Driven Development

3.1 Process Overview

The proposed process, which is based on Model Driven Development, consists of three major phases: “Conceptual Modeling Phase”, “Simulation Design Phase”, and “Verification Phase” (Figure 4).

In the conceptual modeling phase, the modeler analyzes the target world and describes the conceptual model. He/She defines the model elements, for example agents and information, according to the conceptual model framework “Boxed Economy Foundation Model” (BEFM). The products developed in the phase are “Conceptual-Model Class Diagram”, “Activity Diagram”, and “Communication-Sequence Dia-
Figure 3: New Process of Software Development

Figure 4: Major Phases in Our Proposed Process

In the simulation design phase, the modeler designs and implements the simulation model, which is executable program on the platform “Boxed Economy Simulation Platform” (BESP). The modeler translates the conceptual models into simulation models according to the software framework “Foundation Model Framework” (FMFW). The products are “Simulation-Model Class Diagram”, “Statechart Diagram”, “Initial World-Settings”, and the corresponding program codes.

In the verification phase, the modeler runs the simulation and inspects whether the simulation program is coded rightly. If necessary, the modeler returns to the first or second phase and modifies the models.

3.2 Conceptual Modeling Phase

3.2.1 Purpose and Products

The purpose of conceptual modeling phase is to specify what the target system is. The modeler extracts “Agent”, “Behavior”, “Relation”, “Goods”, and “Information” from the target world, and defines them. In addition, he/she describes the activities of agents and the sequence of communications. UML (Unified Modeling Language) is used for describing the model. The products developed in the phase are followings:

- Conceptual-Model Class Diagram
- Activity Diagram
- Communication-Sequence Diagram

3.2.2 Static View

First step is to specify the characters in the target world. The specification is done based on “Boxed Economy Foundation Model” (BEFM). BEFM can be a frame of reference for recognizing the target world (Figure 5). With using the model framework, the modeler can focus on the part of the target world [Iba et al., 2002, Iba et al., 2002].

The modeler extracts the following characters from the target world, and defines types of them in the conceptual-model class diagram.

1UML (Unified Modeling Language) is standard language for object-oriented modeling today. See the reference [Rumbaugh et al., 1999] for more details.
Agent An autonomous actor who does an activity is represented by Agent type. Each individual and social groups such as corporations, governments, families, schools, regional communities, and countries are described as Agents in the model.

Behavior The behavior of the agent is represented by Behavior type. Various activities such as decision-making, production, trade and communication, are described as Behavior in the model. Different Behaviors can be done at the same time by the Agent. A Behavior has an internal state, and the state can be changed by events.

Relation An agent in a model usually has some kind of relationship with other agents rather than being isolated. The relation between agents is represented by Relation type. The relationships, such as friends, spouses, teachers, students, employees, employers, are described as Relation in the model. Relation is an object by which two Agents are connected in a one-way or two-ways direction.

Goods A material/immaterial thing, which is possessed by Agents, is represented by Goods type. For example, automobiles, oil, corn, financial stocks, right of land, books, advertisements, memorandums, water, voices, noises, garbage, and money are described as Goods in the model. Goods often hold Information describing various contents, which we will explain next.

Information Information which is held by Goods or Agents is represented by Information type. Information will never exist alone, and will always be held by Goods or Agents. For example, a newspaper can be modeled as an object that the newspaper article (as Information) is printed on paper (as Goods). And a conversation can be modeled as a combination of the contents (as Information) and the voice (as immaterial and transient Goods). Examples of information possessed by Agents are “memory”, “genetic information”, and “name”.

3.2.3 Dynamic View
Next step is to describing the dynamics of the phenomena with two approaches: “Activity Analysis” and “Communication-Sequence Analysis”.

By the activity analysis, the modeler describes the procedure of agent’s behaviors in an activity diagram. The activity diagram is very similar to a flowchart.

By the communication-sequence analysis, the modeler describes the sequence of the communication among the agents. The agent’s behavior is often done in cooperation with the other behaviors. Thus, the modeler describes the exchange of goods / information in a communication-sequence diagram. The communication-sequence diagram can be used to understand the cooperation of behaviors.

3.2.4 Iteration
Now the modeler has finished the first iteration of conceptual modeling phase, but there is an unfinished task. The rest task is to define the goods and information. Since the modeler ought to describe the communication-sequence diagram, it is easy to know what types of goods and information should be defined.

3.3 Simulation Design Phase
3.3.1 Purpose and Products
The purpose of simulation design phase is to translate the conceptual models into the simulation models (programs). The modeler makes the simulation model based on the software framework “Foundation Model Framework” (FMFW). FMFW is a concrete software framework of the model framework “BEFM” (Figure 6).

UML is also used for describing the model. The products developed in the phase are followings:
- Simulation-Model Class Diagram
- Statechart Diagram
- Initial World-Settings
- Simulation Programs
3.3.2 Static View

The modeler describes the types and classes in “Simulation Model Class Diagram”. It is based on the conceptual model class diagram, which has been developed in the conceptual modeling phase. These diagrams are often same or very similar.

Some classes, however, are added to the class diagram in the phase. First, it is the class for operating simulation rather than the element of the conceptual model. The example is the behavior that manages the order of activating the other behaviors. Second, it is an implemented class to describe behavior and information. This kind of class diagrams is for understanding the computational model rather than the conceptual model.

3.3.3 Dynamic View

The modeler describes the statechart diagram in order to describe the dynamics of the model. In many cases, much time is spent in designing the statechart diagrams in the development process. The modeler designs the statechart diagrams based on the following diagrams, which are developed in the conceptual modeling phase: Communication-Sequence Diagram and Activity Diagram.

As a guideline of finding states of behavior, the point of a leaving arrow in the communication-sequence diagram indicates the beginning point of the state. And the point of a coming arrow indicates the end of the state.

The candidate of the action is the activity in the activity diagram.

Then, the modeler may implement the details of the simulation as a program code. The phase is supported a lot by our tools, which we will discuss in the next section. In the phase, the modeler writes the following program codes if necessary:

- Action Methods in Behavior Class
- Guard-Condition Methods in Behavior Class
- Fields and Methods in Information Class
- Priority Settings of TimeEvent in Model Class

Since the other parts of the simulation programs are generated by the tools, the modeler does not have to write any more codes.

3.3.4 Initialization

The modeler describes the initial settings of simulated world. They are the data for building the simulation at the instance level. The modeler describes the following settings:

- Agent
  - number
  - Behavior
  - Goods
  - Information
- Relation
  - source
  - target
  - direction

Current tools, which we propose in this paper, are not sophisticated enough to transform from design models to program code for a hundred percent. The modeler should write the program code of the action description of agent’s behavior. We, however, try to define patterns of the actions in order to develop more sophisticated tools. Note that the automatic generation of action description is also discussed at the field of UML standardization. See the reference [Mellor and Balcer, 2002].
3.4 Verification Phase

3.4.1 Purpose and Products

The purpose of the verification phase is to run and verify the simulation. The products developed in the phase are followings:

- Verified Simulation Program

3.4.2 Running and Verifying the simulation

The modeler runs the simulation, which he/she has been developed, in order to investigate whether the program works or not. In order to get a reliable result, the simulation should be verified. “Verification” is the inspection whether the simulation program is coded rightly from the conceptual model. The modeler investigates the correspondences between the initial settings and the simulation results.

4 Proposed Tools based on Model Driven Development

4.1 Component Builder

In order to support modeling and designing simulations, we would like to propose “Component Builder” (CB). Component Builder consists of four designers and a composer: Model Designer, Activity Designer, Communication Designer, Behavior Designer and World Composer. They are the tools to generate the program code just by drawing the diagram and setting the parameters with a graphical user interface\(^3\). The correspondence between process and tools is de-
scribed in Figure 7.

4.1.1 Model Designer

Model Designer is a supporting tool for modeling the static view of the simulation (Figure 8). The modeler uses the tool in both phase of conceptual modeling and the simulation design. In the conceptual modeling phase, he/she draw the conceptual-model class diagram. In the simulation design phase, he/she draw the simulation-model class diagram. The tool can generate the program code automatically.

4.1.2 Activity Designer

Activity Designer is a supporting tool for modeling the activity of Agents (Figure 9). The modeler uses the tool for drawing the activity diagram in conceptual modeling phase.

4.1.3 Communication Designer

Communication Designer is a supporting tool for modeling the interaction among Agents (Figure 10). The modeler uses the tool for drawing the communication-sequence diagram in the conceptual modeling phase.

4.1.4 Behavior Designer

Behavior Designer is a supporting tool for modeling the dynamic view of the simulation (Figure 11). The modeler uses the tool for drawing the statechart diagram in the simulation design phase. The tool can generate the program code automatically.

4.1.5 World Composer

World Composer is a supporting tool for modeling the initial state of the simulation world (Figure 12). The modeler uses the tool for setting
the parameters to initialize the simulation in the simulation design phase. The tool can generate the program code automatically.

4.2 Boxed Economy Simulation Platform (BESP)

Another tool what we would like to propose is “Boxed Economy Simulation Platform” (BESP) [Iba et al., 2002, Iba and Takefuji, 2002]. BESP is a software platform to execute and to analyze the agent-based social simulations (Figure 13).

BESP is designed to realize an extensible software application with component-based architecture. The user can obtain the simulation environment which suits the needs, only if he/she sets necessary components into the platform.

There are two kinds of components built into the platform: that is “model component” and “presentation component”. The model component is a software component that implements the model which the user wants to simulate. The model component is made based on “Boxed Economy Foundation Model” (BEFM) and “Foundation Model Framework” (FMFW). The presentation component is a software component for the user interface to operate and to visualize the simulation. The simulation is executed by setting up the social model as the model components and the user interface as the presentation components in BESP. Model components and presentation components are independent each other, communicating indirectly by sending and receiving the events through BESP. Therefore, the modeler simulates his/her original economic model with existing presentation components even if he/she makes only the model components. In contrast, the developer makes his/her original user interface as presentation components that do not specialize in a specific social model.

5 An Example: BakerWorld

5.1 Model Overview

The example which I would like to present here is a simple trade model, “BakerWorld” [Boxed Economy Project, 2003]. The overview of the world is illustrated in Figure 14. There are two types of agents: Baker and Customer, where the baker bakes bread and sells them to the customer. In the following subsections, the diagrams in each phase are shown.
5.2 Conceptual Modeling Phase

In the conceptual modeling phase, we specify the characters in the target world and describe it in the conceptual-model class diagram (Figure 15). The baker is modeled as “BakerAgent”, and the customer is modeled as “CustomerAgent”. BakerAgent has “SalesBehavior”, and CustomerAgent has “ShoppingBehavior”. The relation between them is modeled as “FavoriteShopRelation”.

Next step is to describing the activities of agents with activity analysis. The activities of BakerAgent are “greeting”, “saying price”, “receiving order”, “demanding payment”, “receiving money”, and “giving bread” (Figure 16). The activities of CustomerAgent are “saying hello”, “asking price”, “ordering”, “payment money”, and “receiving bread” (Figure 17).

Third step is to describe the sequence of the communication among the agents (Figure 18). CustomerAgent sends the message “Hello!” to BakerAgent, then the BakerAgent replies the message “May I help you?”. After that, CustomerAgent asks “How much is it?”, and BakerAgent replies “100 yen”. CustomerAgent says “I want 3”, then BakerAgent calculates the sum and says “300 yen, please”. Finally, they exchange MoneyGoods and BreadGoods. The communication can be described in the communication-sequence diagram (Figure 18).

The rest task is to define the goods and information. For Goods, there are BreadGoods and MoneyGoods (Figure 19). For Information,
there are PriceInformation and OrderInformation (Figure 20).

5.3 Simulation Design Phase

In the simulation design phase, we modify the class diagram, which has been developed in the conceptual modeling phase. Then, we describe the statechart diagram of the agent’s behaviors. Figure 21 and 22 show the statechart diagram of ShoppingBehavior and SalesBehavior respectively. In addition, it is necessary to implements some action methods in Behavior classes. For example, the following source code is a method of ShoppingBehavior.

```java
protected void sayingHelloAction() {
    MessageInformation message = new MessageInformation("Hello!");
    this.sendInformation(BakerWorldModel.RELATIONTYPE_FavoriteShopRelation, BoxTownModel.BEHAVIORTYPE_SalesBehavior, message);
}
```

Next step is describing the initial settings of simulated world. The followings are the data for

Figure 19: Goods in the Conceptual Model Class Diagram for BakerWorld

Figure 20: Information in the Conceptual Model Class Diagram for BakerWorld

Figure 21: Statechart Diagram of ShoppingBehavior for BakerWorld
Figure 22: Statechart Diagram of SalesBehavior for BakerWorld

initialization:

- Agent
  - BakerAgent
    * number = 1
    * Behavior = SalesBehavior
  - CustomerAgent
    * number = 1
    * Behavior = ShoppingBehavior

- Relation
  - FavoriteShopRelation
    * source = CustomerAgent
    * target = BakerAgent
    * direction = one-way

5.4 Verification Phase

Finally, we run the simulation in order to investigate whether the program works or not. There are two types of agents on the screen: BakerAgent and CustomerAgent (Figure 23). The BakerAgent sells BreadGoods to the CustomerAgent.

6 Conclusion

In this paper, we proposed the process and tools for Model Driven Development of agent-based social simulations. The tools are opened to public on http://www.boxed-economy.org/. Creating the foundation for the social simulations study is an oversized project for our members to complete. We would like to realize it by collaborating with many researchers in various fields. Please contact us, if you are interested in our challenge.
